

Frozen collapse rule fails to control false positives under array divergence

A Predeclared domain-shift design

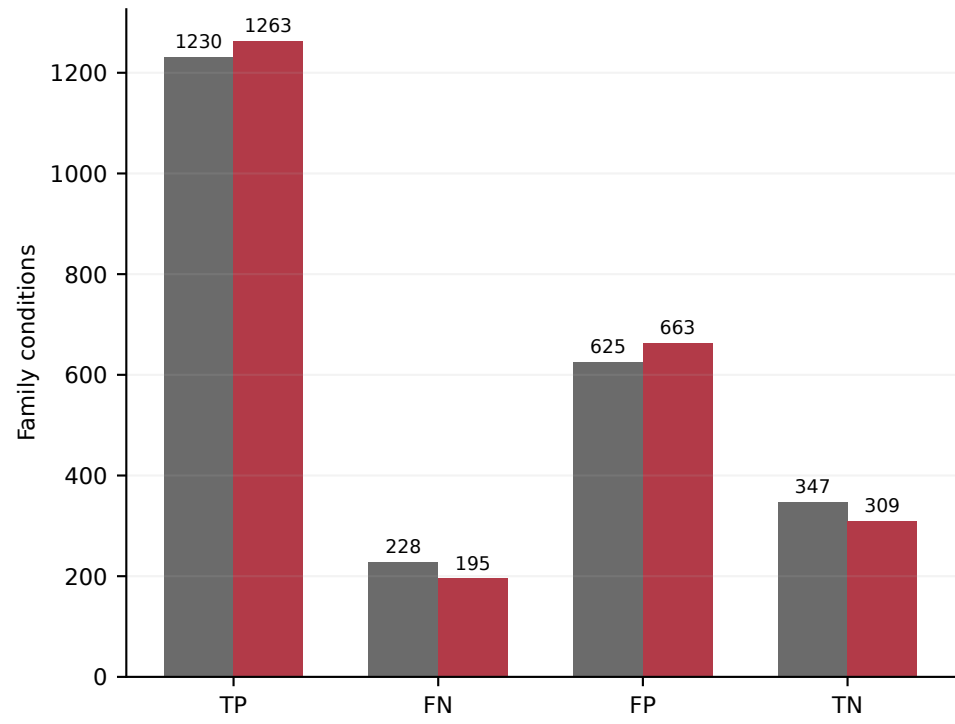

Fresh genomes	3	seeds 5401-5403
Unit divergence	3	1%, 3%, 5% substitutions
Array structures	2	one or three segments
Paired conditions	2,430	all baseline and frozen rows
Multi-k unavailable	270	retained as NA

Frozen exact-copy rule applied without domain-shift fitting

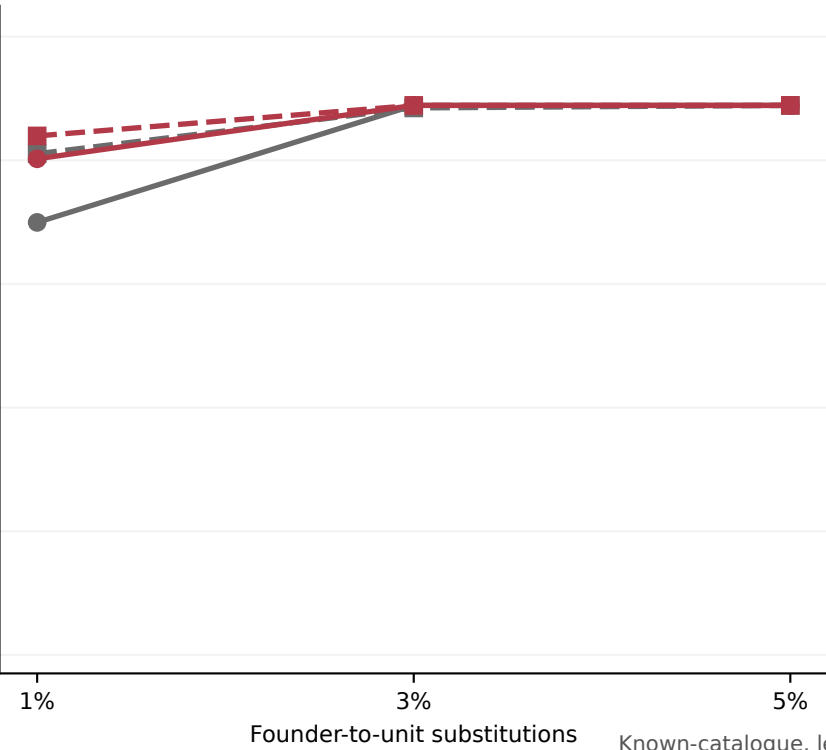

B Overall domain-shift metrics

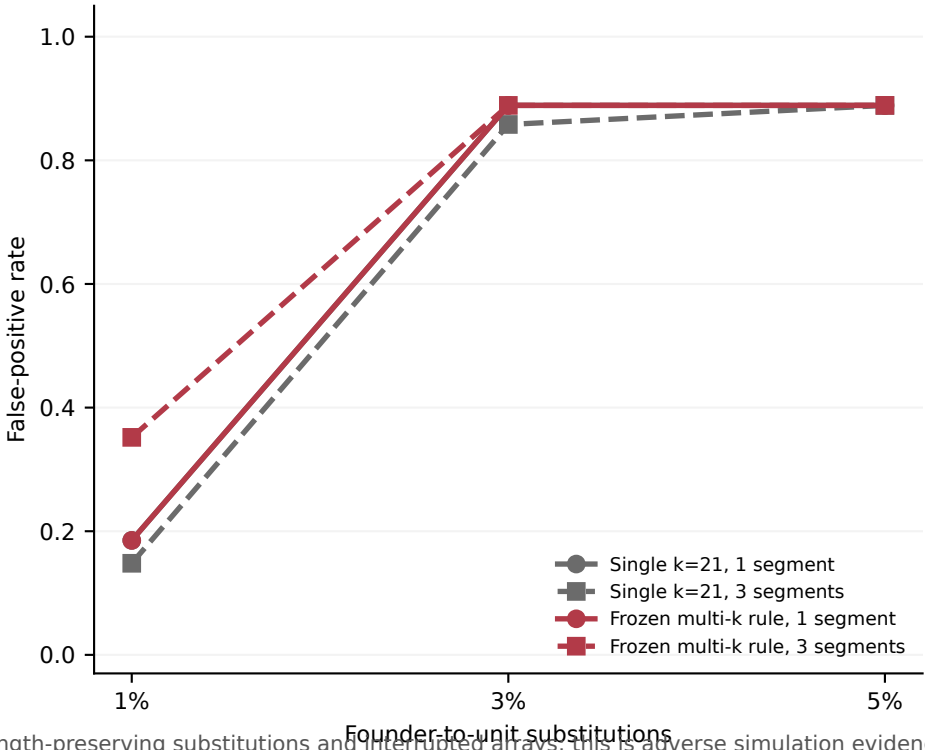

C Confusion counts

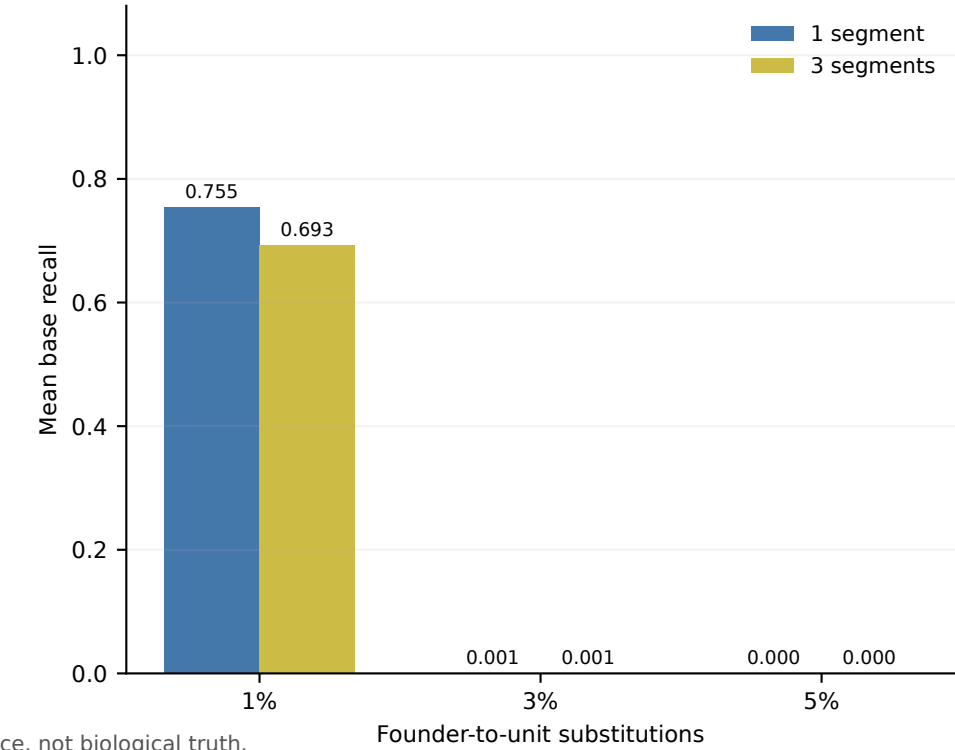

D Sensitivity by divergence

E False-positive rate by divergence

F Full-assembly localization

Known-catalogue, length-preserving substitutions and interrupted arrays, this is adverse simulation evidence, not biological truth.
