

Figure 4 | Improved assemblies preferentially recover read-prioritized repeat families

A Two historical-to-newer assembly comparisons

Primary denominator: ≥ 15 kb localized in the newer assembly

Newer assemblies are reference proxies, not absolute biological copy-number truth.

B Ey15-2: representation in historical and newer assemblies

Every point is one read-derived family in the frozen primary denominator

C Ey15-2: read deficit versus assembly gain

Deficit and assembly gain retain separate meanings

D Macadamia: representation in historical and newer assemblies

Every point is one read-derived family in the frozen primary denominator

E Macadamia: read deficit versus assembly gain

Deficit and assembly gain retain separate meanings

F Read prioritization matches preferential recovery

Complete match in each frozen primary family set

Ey15-2	8/8 read-prioritized & recovered	11/11 not prioritized & not recovered
Macadamia	2/2 read-prioritized & recovered	41/41 not prioritized & not recovered

This is a retrospective reference-proxy result, not an independent population accuracy estimate.

Continuous values are read-assembly abundance deficits and assembly gains, not physical missing-base truth. Full family tables and denominator sensitivities remain in the evidence archive.
